**[ABSTRACT]****TITLE**

5 MANUFACTURING METHOD OF PHOSPHOR OR SCINTILLATOR SHEETS AND PANELS  
SUITABLE FOR USE IN A SCANNING APPARATUS

In a method for coating a phosphor or a scintillator layer onto  
a flexible substrate, within a sealed zone maintained under vacuum  
10 conditions, by the step of vapour deposition, said phosphor or  
scintillator layer is, continuously or discontinuously, deposited  
onto said substrate, and said substrate is deformed at least before,  
during or after said step of vapour deposition, in order to provide  
the manufacturer, by a process of exceptionnally high yield, with  
15 large deposited phosphor or a scintillator sheets having constant  
speed and image quality properties, further offering availability of  
all formats as desired for screens, plates or panels ready-for-use  
in a scanning apparatus in computed radiography, screen/film  
radiography and direct radiography.

**[DESCRIPTION]**

## FIELD OF THE INVENTION

5

The present invention relates to a particular method of coating a layer from a vapour flow of raw materials on a flexible substrate. More particularly the present invention is related to the manufacturing or production of scintillator or phosphor sheets, used in screens, panels or plates suitable for use in high energy radiation detection and imaging and, more particularly, in computed radiography, screen/film radiography and direct radiography.

## 15 BACKGROUND OF THE INVENTION

In radiography the interior of objects is reproduced by means of penetrating radiation, which is high energy radiation also known as ionizing radiation belonging to the class of X-rays,  $\gamma$ -rays and high-energy elementary particle rays, e.g.  $\beta$ -rays, electron beam or neutron radiation.

For the conversion of penetrating radiation into visible light and/or ultraviolet radiation "luminescent" substances, called "phosphors", are used. Cathodoluminescent phosphors employed e.g. in CRT screens exhibit two related luminescent characteristics: fluorescence and phosphorescence. Fluorescence is the luminescent build-up or emission of light released from the phosphor during the time of electron beam excitation. Phosphorescence is the emission of light from the phosphor occurring after the cessation of electron beam excitation. The duration of phosphorescence, or rate of decay of afterglow, is denoted as persistence, usually expressed as a measurement of time required for the phosphorescence in order to reduce or decay to a ten percent level of steady state fluorescent brightness.

35 In known X-ray image intensifiers for example as disclosed in US-A 3,838,273, the input screen comprises a substrate such as glass

- 3 -

or aluminum on which is deposited an X-ray sensitive radiation conversion layer, commonly referred to as a fluorescence layer or scintillator.

In a conventional radiographic system an X-ray radiograph is  
5 obtained by X-rays transmitted imagewise through an object and converted into light of corresponding intensity in a so-called intensifying screen (X-ray conversion screen) wherein phosphor particles absorb the transmitted X-rays and convert them into visible light and/or ultraviolet radiation to which a photographic  
10 film is more sensitive than to the direct impact of X-rays. In practice the light emitted imagewise by said screen irradiates a contacting photographic silver halide emulsion layer film which after exposure is developed to form therein a silver image in conformity with the X-ray image.

15 As described e.g. in US-A 3,859,527 an X-ray recording system has meanwhile been developed wherein photostimulable storage phosphors are used having, in addition to their immediate light emission (prompt emission) on X-ray irradiation, the property to store temporarily a large part of the X-ray energy. Said energy is  
20 set free by photostimulation in the form of fluorescent light different in wavelength from the light used in the photostimulation. In said X-ray recording system the light emitted on photostimulation is detected photoelectronically and transformed into sequential electrical signals. A storage screen or panel coated with such  
25 phosphors is exposed to an incident pattern-wise modulated X-ray beam and as a result thereof energy is temporarily stored in the coated storage phosphors, corresponding with the X-ray radiation pattern. At some interval after the exposure, a beam of visible or infra-red light scans the panel in order to stimulate the release of  
30 stored energy as light that is detected and converted to sequential electrical signals which are processed to produce a visible image. Stimulation light can be transformed into an electric signal by making use of a photoelectric conversion element such as e.g. a photo-multiplier. It is clear that the phosphor should store as  
35 much as possible of the incident X-ray energy and emit as little as

- 4 -

possible of the stored energy until stimulated by the scanning beam. This is called "digital radiography" or "computed radiography".

Recently, in the hospitals the tendency is increasing to obtain X-ray images on computer monitor immediately after X-ray exposure of the patient. By storing and transmitting that digitized information efficiency and speed of diagnosis is enhanced. Accordingly "direct radiography" providing directly digital diagnostic X-ray images, after exposure of an adapted detector panel in a radiographic apparatus, becomes preferred instead of the conventional screen/film system. The X-ray quanta are transformed into electric signals by making use of a solid-state flat detector as "image pick-up" element. Such a flat detector is commonly called a "flat panel detector" and is two-dimensionally arranged. Making use therein of a photoconductive material as a detecting means, such as a-Se, in which the negative electrical charge of an electron and the positive electrical charge of a hole are generated by the X-ray energy, said X-ray energy is directly converted into those separated electrical charges. The electrical charge thus obtained is read out as an electric signal by the read-out element, two-dimensionally arranged in a fine area unit.

Further on an indirect type flat-panel-detector is known, in which the X-ray energy is converted into light by a scintillator, and in which the converted light is converted into the electric charge by the photoelectric conversion element such as a-Si two-dimensionally arranged in a fine area unit. The electrical charge is read out again as an electric signal by the photoelectric conversion read-out element, two-dimensionally arranged in a fine area unit.

Moreover a direct radiography detector is known in which the X-ray energy is converted into light by a scintillator, and wherein the converted light is projected on one or more CCD or CMOS sensors which are arranged matrix-wise in the same plane, through a converging body such as a lens or optical fiber. In the inside of the CCD or CMOS sensor, via photoelectric conversion, and charge-voltage conversion, an electric signal is obtained in every pixel.

- 5 -

This type of detector is also defined, therefore, as a solid state plane detector.

The image quality that is produced by any radiographic system using phosphor screen or panel, and more particularly, within the scope of the present invention, in a digital radiographic system, largely depends upon the construction of the phosphor screen. Generally, the thinner a phosphor screen at a given amount of absorption of X-rays, the better the image quality will be. This means that the lower the ratio of binder to phosphor of a phosphor screen, the better the image quality, attainable with that screen or panel, will be. Optimum sharpness can thus be obtained when screens without any binder are used. Such screens can be produced, e.g., by physical vapour deposition, which may be thermal vapour deposition, sputtering, electron beam deposition or other of phosphor material on a substrate. Such screens can also be produced by chemical vapour deposition. However, this production method can not be used to produce high quality screens with every arbitrary phosphor available. The mentioned production method leads to the best results when phosphor crystals with high crystal symmetry and simple chemical composition are used. So in a preferred embodiment use of alkali metal halide phosphors in storage screens or panels is well known in the art of storage phosphor radiology and the high crystal symmetry of these phosphors makes it possible to provide structured, as well as binderless screens.

It has been disclosed that when binderless screens with an alkali halide phosphor are produced it is beneficial to have the phosphor crystals deposited as some kind of piles or pillar-shaped blocks, needles, tiles, etc., in order to increase the image quality that can be obtained when using such a screen. In US-A 4,769,549 it is disclosed that the image quality of a binderless phosphor screen can be improved when the phosphor layer has a block structure, shaped in fine pillars. In US-A 5,055,681 a storage phosphor screen comprising an alkali halide phosphor in a pile-like structure is disclosed. In EP-A 1 113 458 a phosphor panel provided with a selected vapour deposited CsBr:Eu phosphor layer is disclosed,

- 6 -

wherein the binderless phosphor is present as fine needles in favour of an optimized image quality.

It is clear that, from a point of view of homogeneity of layer thickness and chemical composition of the scintillator, in favour of  
5 a constant speed, image quality and diagnostic reliability, it is of utmost importance to provide said constant composition and layer thickness over the whole two-dimensional panel surface in the production of the storage phosphor plates. A homogeneous coating profile should thus be strived for.

10 Manufacturing procedures making use of deposition techniques as in US-A 4,449,478 wherein an arrangement for coating substrates in an apparatus for vacuum deposition comprises a rotatable substrate holding structure in a form of a plate, provide coated panels limited in number and in coated surface. Moreover, when square or  
15 rectangular panels are desired, quite a lot of expensive residue is created while not being deposited onto the plate, rotating with a circular symmetry above the vapour source. In addition, when depositing material from a fixed source onto such a rotating substrate, it is difficult to obtain a layer with a constant  
20 thickness. Circles on the substrate, having the rotation axis as centre will have identical deposition history. This creates a centro-symmetric thickness profile, which means that the thickness of the deposited layer is constant along neither of the sides of a rectangular substrate, unless special precautions are taken, e.g.  
25 use of a mask which will however lead to material losses.

Manufacturing procedures making use of deposition techniques as in US-Application 2003/0024479 wherein an arrangement for coating rigid substrates, batch wise (plate per plate) in an apparatus for vacuum deposition comprises a substrate holder conveyed from a  
30 loading chamber to an unloading chamber by a conveying mechanism, provide coated panels limited in process yield. Another batch process has been described in US-A 6,402,905, where commonly a vapour deposition coating process is applied by which vapour is deposited onto a substrate that rotates around one axis that is  
35 perpendicular to the deposition area, as commonly applied in the state of the art, and wherein a system and method for controlling

- 7 -

and compensating unevenness of the deposition thickness distribution on a substrate has been described.

In such a batch process a coating failure will generally lead to the complete loss of a panel. Moreover there will always be a high loss of raw materials in such batch processes. Lack of deformability of the substrate also limits the format of the coating of a phosphor or scintillator layer on a substrate to the largest cross section of the vacuum deposition chamber.

10

#### OBJECTS AND SUMMARY OF THE INVENTION

Therefore it is an object of the present invention to provide a method of producing phosphor or scintillator plates or panels, wherein the layer thickness in the manufacturing process is constant over large surface areas.

It is another object of the present invention to provide phosphor plates of differing tailor-made sizes, all resulting from the same deposition process, wherein said plates moreover show homogeneity in speed and sharpness over the whole area of the plates, irrespective of their dimensions.

A still further object of the present invention is to provide a method of producing phosphor plates or panels on a substrate with a surface area that is much larger than the area of a single plate or panel manufactured in a batch process, e.g. preferably more than 1.5 times larger, more preferably more than 5 times larger and even most preferably more than 10 times larger.

Still another object is related with the yield of the process, thereby obviating undesired losses of expensive raw materials.

Furtheron it is still another object of the present invention to provide a method of producing phosphor or scintillator plates or panels on very large flexible substrates, cutting these large areas in desired formats and protecting these flexible plates or panels against physical, chemical or mechanical damage, or a combination thereof.

- 8 -

Other objects will become apparent from the description hereinafter.

The above-mentioned advantageous effects have been  
5 advantageously realized by a particular manufacturing method having the specific features set out in claim 1. Specific features for preferred embodiments of the invention are set out in the dependent claims and in the drawings.

Further advantages and embodiments of the present invention  
10 will become apparent from the following description and drawings...

#### BRIEF DESCRIPTION OF THE DRAWINGS

Following Figures represent an illustration of different  
15 embodiments of configurations related with the substrate to be coated and the apparatus wherein the coating process takes place. It is clear that these Figures, showing preferred embodiments of the coating methods according to the present invention, are in no way limited thereto.

20

Fig. 1 shows a cylindrical vacuum chamber (1), containing an electrically heated oven (2) and a refractory crucible, tray or boat (3) containing a mixture of raw materials (4) which should be vaporized in order to be deposited onto a flexible sheet (5). The  
25 flexible sheet (5) is supported by a cooled - supporting - roller (6), thermally isolated from said flexible sheet (5) by a thermal isolation layer (7) and by heat-resisting coiled springs (8) mounted circumferentially onto said cylinder, further interconnecting both ends of said flexible sheet (5). Heating of said flexible sheet (5)  
30 proceeds by means of infrared heater (9) and reflector cage (10). Pyrometer (11) allows measurement of the temperature. The flexible sheet (5) is moving continuously or discontinuously in a forward direction through a vapour stream (16) provided by the heated mixture of raw materials (4) as a source for said vapour stream  
35 (16). Baffles (12) and (13) restrict vapour deposition to a selected part of sheet (5), mounted onto the roller (6). Refractory

- 9 -

boat or tray (3) is covered with metallic raster (14), which avoids formation of pits (and unevenness) on the coated phosphor layer, deposited onto the flexible sheet (5). A cooled baffle (17) may be moved to shut off the surface to be coated from or expose the surface to be coated to the vapour stream.

Optionally there can be a separation (15) between the evaporation part (18) and the heating part (19).

Fig. 2 shows vacuum chamber (1), a flexible sheet (5) that is stretched around four conveying rollers (20), moving continuously or discontinuously in a forward direction through a vapour stream (16), provided by the mixture of raw materials (4) present in the tray or boat (3) and heated to provide a vapour source generating said vapour stream (16), in order to provoke a phosphor layer to be deposited onto the flexible sheet (5) in one step (passage or transit through the vapour stream (16) in one step) or in several successive steps (more than one passage or transit through the vapour stream (16)) and wherein the flexible sheet (5) does not leave the vacuum chamber (1). The illustrated travelling pathway (21) of the flexible sheet (5) is not limitative. Another construction could be the use of smaller flexible sheets that are mounted on a flexible support material that is stretched around the conveying rollers (20).

Fig. 3 shows vacuum chamber (1), a flexible sheet (5) that is stretched around four conveying rollers (20), moving successively in a forward and backward direction and continuously or discontinuously through a vapour stream (16), provided by the mixture of raw materials (4) present in the tray or boat (3) and heated to provide a vapour source generating said vapour stream (16), in order to provoke a phosphor layer to be deposited onto the flexible sheet (5) in several successive steps (more than one passage or transit through the vapour stream (16)) and wherein the flexible sheet (5) does not leave the vacuum chamber (1). The travelling pathway (21) of the flexible sheet (5) as represented in this Fig. 3 is not limitative. Another construction could be the use of smaller

- 10 -

flexible sheets that are mounted on a flexible support material that is stretched around the conveying rollers (20).

Fig. 4 shows vacuum chamber (1), a flexible sheet (5) that is stretched around four conveying rollers (20), moving continuously or discontinuously in a forward direction through a vapour stream (16) provided by the mixture of raw materials (4) present in the tray or boat (3) and heated to provide a vapour source generating said vapour stream (16), in order to provoke a phosphor layer to be deposited onto the flexible sheet (5), in one step (passage or transit through the vapour stream (16) in one step) or in several successive steps (more than one passage or transit through the vapour stream) and wherein the flexible sheet (5) leaves the vacuum chamber (1). The illustrated travelling pathway (21) of the flexible sheet (5) is not limitative. Another construction could be the use of smaller flexible sheets that are mounted on a flexible support material that is stretched around the conveying rollers (20).

Fig. 5 shows vacuum chamber (1), a flexible sheet (5) that is stretched around four conveying rollers (20), moving successively in a forward and backward direction and continuously or discontinuously through a vapour stream (16) provided by the mixture of raw materials (4) present in the tray or boat (3) and heated to provide a vapour source generating said vapour stream (16), in order to provoke a phosphor layer be deposited onto the flexible sheet (5) in several successive steps (more than one transit or passage through the vapour stream) and wherein the flexible sheet (5) leaves the vacuum chamber (1). The illustrated travelling pathway (21) of the flexible sheet (5) is not limitative. Another construction could be the use of smaller flexible sheets that are mounted on a flexible support material that is stretched around the conveying rollers (20).

Fig. 6 shows a flexible sheet substrate (5) mounted around one rotating support roller (6), in a vacuum chamber (1), moving

- 11 -

continuously or discontinuously in a forward (or backward) direction through a vapour stream (16) provided by the mixture of raw materials (4) present in the tray or boat (3) and heated to provide a vapour source generating said vapour stream (16), in order to  
5 provoke a phosphor layer to be deposited onto the sheet (5) in one step (one rotation) or in several successive steps (more rotations).

Fig. 7 shows a flexible sheet substrate (5) mounted around one rotating support roller (6), in a vacuum chamber (1), moving  
10 successively in a forward and backward direction and continuously or discontinuously through a vapour stream (16), provided by the mixture of raw materials (4) present in the tray or boat (3) and heated to provide a vapour source generating said vapour stream (16), in order to provoke a phosphor layer to be deposited onto the  
15 flexible sheet (5) in several successive steps.

Fig. 8 shows a vacuum chamber (1) for vapour coating, wherein a roll supply of material (23) (unwinding roller) is fed out in continuous sheet form or web (22). The web is conveyed over a  
20 guiding roller (6) and collected on a winding roll (24). The continuous sheet form (22) or web is moving continuously or discontinuously in a forward direction through a vapour stream (16) provided by the mixture of raw materials (4) present in the tray or boat (3) and heated to provide a vapour source generating said  
25 vapour stream (16), in order to provoke a phosphor layer to be deposited onto the web (21) and wherein the unwinding roller (23) and the winding roller (24) are in the vacuum chamber (1). A cooled baffle (17) may be moved in order to shut off the surface to be coated from or in order to expose the surface to be coated to the  
30 vapour stream. Baffles (12) and (13) restrict vapour deposition to a selected part of web (22). Optionally there can be a separation by plates (15) between the evaporation part (18) and the winding part (25) in the vacuum chamber (1). Optionally, in the case that the raw materials get exhausted, a source of raw material supply  
35 (26) can add raw materials, with the aid of a guiding mechanism

- 12 -

(27), to the site where it should be vaporized. Multiple sources may of course also be used.

Fig. 9 is analogous with Fig. 8, but is different in that the continuous sheet form or web (22) is moving continuously or discontinuously in a successively forward and backward direction through a vapour stream (16), provided by the mixture of raw materials (4) present in the tray or boat (3) and heated to provide a vapour source generating said vapour stream (16), in order to provoke a phosphor layer to be deposited onto the support in successive steps and wherein the unwinding or supply roller (23) and the winding roller (24) are in the vacuum chamber (1).

Fig. 10 shows a vacuum chamber (1), a web (22) that is supplied by an unwinding roller or supply roller (23), conveyed over a guiding roller (6) and wound up on a winding roller (24), moving continuously or discontinuously in a forward direction through a vapour stream (16), provided by the mixture of raw materials (4) present in the tray or boat (3) and heated to provide a vapour source generating said vapour stream (16), in order to provoke a phosphor layer to be deposited onto the support web (21) and wherein the unwinding roller (23) and the winding roller (24) are outside the vacuum chamber (1), in the surrounding ambient atmosphere. Not shown in the Fig. 10 (but optionally present as in Fig. 9, if the raw materials get exhausted) is a source of raw materials supplying the raw materials (26) (see Fig. 9), with the aid of a guiding mechanism (27) (see Fig. 9), to the site where said raw materials should be vaporized. Multiple sources may of course also be used.

30

Fig. 11 shows a vacuum chamber (1), a web support (22) that is supplied by an unwinding roller (23), conveyed over a guiding roller (6) and wound up on a winding roller (23), moving continuously or discontinuously in a forward and backward direction through a vapour stream (16), provided by the mixture of raw materials (4) present in the tray or boat (3) and heated to provide a vapour source

35

- 13 -

generating said vapour stream (16), in order to provoke a phosphor layer to be deposited onto the support web (22) in successive steps and wherein the unwinding roller (23) and the winding roller (24) are outside the vacuum chamber (1) in the ambient atmosphere (28).

5 Not shown in the Fig. 11 (but optionally present as in Fig. 9, if the raw materials get exhausted) is a source of raw materials supplying the raw materials (26) (see Fig. 9), with the aid of a guiding mechanism (27) (see Fig. 9), to the site where said raw materials should be vaporized. Multiple sources may of course also  
10 be used.

#### DETAILED DESCRIPTION OF THE INVENTION

15 According to the present invention a method for coating is provided of a phosphor or a scintillator layer onto a flexible substrate, within a sealed zone maintained under vacuum conditions - also called "vacuum chamber"-, by the step of vapour deposition in a coating zone onto said flexible substrate, wherein said phosphor or  
20 scintillator layer is (continuously or discontinuously) deposited onto said flexible substrate, characterized in that said substrate is deformed at least before, during or after said step of vapour deposition. Configurations wherein said flexible substrate is mounted onto a roller or wherein it is guided over one or more  
25 roller(s) or wherein said substrate is, at least partially, guided over one or more guiding frame(s), when guided over one or more roller(s) are particularly envisaged.

Within the scope of the present invention the term "flexible substrate" should be understood as "reversably deformable supporting  
30 or supported layer in form of a sheet, web or roller", the surface area of which should be coated with a phosphor or scintillator material. Such a substrate should be present as a flexible sheet, also called "web" when present as flexible material, wound up in  
35 form of a roller. When large distances should be bridged in the coating apparatus and, optionally, outside thereof, in the coating

- 14 -

process of the present invention, the web support should preferably be guided over a frame or over rollers in order to avoid undesired sagging. Differing configurations in order to guide the substrate are thus available in the sealed zone of the coating apparatus or, optionally, outside said sealed zone as illustrated in the Figures, without however being limited thereto.

According to the coating process or method according to the present invention, said substrate is, at least partially, moving over one or more roller(s) and/or guiding frame(s). This has been illustrated in the Figures 1-11.

It is an essential feature that the flexible substrate is deformed at least before, during or after said step of vapour deposition, by being mounted onto a roller or by being guided over one or more roller(s), in the vacuum chamber. Use of rigid plates or substrates, that cannot be deformed do not provide an "on-line" vapour deposition, so that a larger surface is coated, but opposite thereto require a "batch process". When the term "deformed" is used in the following description, it is understood as "deformed by being mounted onto a roller or by being guided over one or more roller(s)". Guiding means, such as a guiding roller or a guiding frame provide to bring the sheet or web in a condition, as desired in a flat, concave or convex screen, plate or panel in specific applications suitable for use in high energy radiation detection and imaging and, more particularly, in computed radiography, screen/film radiography and direct radiography as set forth.

Guiding means deforming the flexible substrate have been shown in the Figures 1-11, without however being limited thereto. It is essential to deform the substrate at least once before, during or after passing the vapour stream provided by the mixture of raw materials present in the crucible, tray or boat and heated to provide a vapour source generating said vapour stream to become deposited onto the flexible support or substrate.

- 15 -

An illustration of deforming the flexible substrate (at least) before (and not during) coating wherein the substrate is running or travelling as a "flat substrate" through the vapour stream has been schematically illustrated in the Figures 2, 3, 4 and 5. Deformation  
5 in that case is performed at the conveying roller positions of the web, wherein those conveying rollers are positioned within the vacuum chamber as in the Figures 2 and 3, or outside the vacuum chamber as in the Figures 4 and 5.

10 An illustration of deforming the flexible substrate (at least) after (and not during) coating, has been given in the same Figures, wherein it is further illustrated that the flexible substrate runs like a "flat" web (whether or not conveyed over a frame) over the vapour stream. Depending on the distance between the rollers and  
15 weight of the web, even when being stretched, the web may be slightly curved when passing the vapour stream. It remains essential to get a uniform coating over the whole width of the web and it is clear that uniformity over its length can only be performed when the web is travelling continuously or discontinuously  
20 at a constant rate, whether or not interrupted at constant intervals, e.g. at a constantly "pulsed" rate, such that the amount of deposited material is constant. The amount of deposited material results from a combination of moving speed of the support or substrate and amount of evaporated material per time unit.

25 An illustration of deforming the flexible substrate during coating (but also before, at the position of the "supplying" unwinding roller and after, at the position of the "collecting" (up)winding rollers), has been given in the Figures 8, 9, 10 and 11.

30 In the Figures 1, 6 and 7 the flexible substrate is mounted onto a (cooled) support roller and deformed from being presented as a flat substrate at the vapour deposition area in the vapour stream. In those Figures 1, 6 and 7, the substrate is thus continuously  
35 deformed from being flat, and held in a constantly curved position, while being rotated over the (optionally cylindrical) support

- 16 -

roller. It is clear that it is not an object to use the coated flexible support sheet in such a curved position, but to deform it after demounting or removing the coated sheet from the support roller. It is contemplated to deform the coated substrate in a way  
5 in order to get a flat, convex or concave scintillator or storage phosphor sheet or panel.

In a further preferred embodiment according to the present invention said phosphor or scintillator layer is (continuously or  
10 discontinuously, as explained before) deposited onto said flexible substrate, and said substrate is continuously supplied, either in a forward direction (Fig. 1, 2, 4, 8 and 10) or in a forward and backward direction (Fig. 3, 5, 7, 9 and 11). Accordingly the substrate to be coated is continuously supplied, as most preferred  
15 embodiment in practicing the present invention. This has been illustrated in all of the Figures 1-11 and indeed is essential in order to have an "on-line" vacuum deposition, providing the advantages of large, uniformly coated areas of scintillator or phosphor sheets, panels or webs to be cut into desired formats.

20

Moreover the present invention advantageously provides an accessible manufacturing method of phosphor or scintillator plates, sheets or panels, wherein the yield of the manufacturing process is unexpectedly high, as undesired losses of expensive raw materials  
25 and coated sheets or panels, are avoided. A constant coating quality furtheron avoids spill of material, due to deviations from required specifications as a constant layer thickness and a desired homogeneity and phosphor speed over large surface areas are attained.

30

With respect to availability to deform the flexible substrate, it has unexpectedly been shown that, for a phosphor or scintillator layer with a thickness of up to 500  $\mu\text{m}$ , and even up to 1000  $\mu\text{m}$ , no problems are encountered with respect to occurrence of undesirable  
35 cracks when said flexible substrates have been deformed at least before, during or after said step of vapour deposition, by being

- 17 -

mounted onto a roller or by being guided over one or more roller(s). The present invention describes a method to manufacture, in one and the same manufacturing process and on the same substrate, all desired formats of panels or screens for use in computed  
5 radiography, screen/film radiography and direct radiography.

The possibility to deform the flexible substrate creates the opportunity to coat large surface areas of such a flexible substrate with the vapour deposited scintillator or phosphor within a limited  
10 geometrical space.

In the coating process according to the present invention, said phosphor or scintillator layer (after having been coated onto said flexible substrate) is deposited onto an area of said flexible  
15 substrate, exceeding the area of a phosphor or scintillator screen, panel or plate ready-for-use with at least 50%. More preferably in the coating process according to the present invention, said phosphor or scintillator layer is deposited onto an area of said flexible substrate, exceeding the area of a phosphor or scintillator  
20 screen, panel or plate ready-for-use with at least a factor of 5, and even more preferably with at least a factor of 10. The expression "screen, panel or plate ready-for-use (in a scanning apparatus)" refers to a well-known area of 14" x 17" (35.6 cm x 43.2 cm) as being commercially available.

25

According to the present invention said coating process is further comprising the step of cutting said substrate, carrying said deposited phosphor or scintillator layer.

30

Another aspect related with the coating process according to the present invention is that said flexible substrate is passing, at least once, through said coating zone by a continuous or discontinuous motion in a forward sense. Such a movement has been indicated by the arrows present in the Figures 3 and 5 for moving  
35 sheets, plates or panels and in the Figures 7, 9 and 11 for a moving web substrate. Whereas a "continuous" movement is indicating that

- 18 -

there is no interruption and, more preferably a movement at a constant rate, "discontinuous" means that the movement is e.g. pulsed, more preferably at a constant pulse frequency. From the Figures 1, 6, 8 and 10 it is clear that a flexible substrate mounted  
5 on a support roller is passing more than once through the vapour stream until the desired phosphor or scintillator coating layer thickness is attained. Same is learnt from the Figures 2 and 4 where the flexible substrate is passing the vapour stream as a flat substrate.

10

In still another embodiment according to the coating process of the present invention said flexible substrate is moving (through said coating zone), in (continuous or discontinuous) successive steps of forward and backward motion, whether or not interrupted  
15 inbetween said successive steps. Such an interrupted movement can be applied to all of the Figures 1 to 11. So the movement may be controlled by pulses from any driving force, as e.g. from a motor. More in particular, looking at the Figures, it may even be advantageous for the configurations illustrated in the Figures 3, 5,  
20 7, 9 and 11, where the movement should be interrupted as the moving direction changes in a "swinging" way. While travelling in a forward or backward direction, the movement may however proceed continuously or discontinuously (e.g. pulsed). Each change in direction however implies that there is at least a sudden moment  
25 (when changing) that the movement is temporarily stopped. This interruption may be restricted thereto or may be extended up to a well-defined time.

An advantageous aspect of a "swinging movement", with moving  
30 cycles from one to an opposite direction, is related with the frequent material deposition and formation of a plurality of layers onto the flexible substrate.

In still another embodiment according to the coating process of  
35 the present invention said substrate is moving (or running) over at least one unwinding or supplying roller and/or one roll up or

- 19 -

winding roller, wherein none, one or both of said roller type(s) is(are) present outside said sealed zone. This has e.g. been illustrated in the Figures 8 and 9 (none outside, both inside the sealed zone of the coating apparatus) and in the Figures 10 and 11 (both rollers outside the coating apparatus) respectively, as explained hereinbefore. Such a configuration is only applicable if enough free space is available in the coating apparatus, and, more particularly in the sealed zone.

In the coating process according to the present invention, said substrate is a self-supporting sheet, plate, web or panel. In another embodiment according to the present invention, said substrate is a roller web. In still another embodiment of the coating process according to the present invention said substrate is supported by a substrate holder.

According to the coating process of the present invention said (flexibly moving) substrate is selected from the group consisting of glass, a ceramic material, a polymeric material or a metal.

According to the coating process of the present invention the moving substrate support for the layer to be deposited is preferably selected from the group consisting of glass, polyethylene terephthalate, polyethylene naphthalate, polycarbonate, polyimide, aluminum, Pyrex<sup>®</sup>, polymethylacrylate, polymethylmethacrylate, sapphire, zinc selenide, Zerodur<sup>®</sup>, a ceramic layer and a metal or an alloy selected from the group of aluminum, steel, brass and copper. It should not be limited thereto as in principle, any metal or synthetic material resisting irreversible deformation, e.g. as by melting, after addition of energy to the extent as commonly applied in the coating process of the present invention, is suitable for use. Particularly preferred as flexibly moving substrate in the coating process of the present invention is aluminum as a very good heat conducting material allowing a perfect homogeneous temperature over the whole substrate.

- 20 -

In a coating process of the present invention said metal substrate is an aluminum layer, previously coated with a protective layer being an oxide or a polymeric compound layer, present on at least a side of said substrate moving through said vapour stream (thus on the side of said substrate whereupon vapour deposition is applied).

In a further preferred embodiment of the coating process of the present invention, said metal substrate is an anodized aluminum layer having a thickness of less than 600  $\mu\text{m}$ , and even more preferably said thickness is in the range from 100  $\mu\text{m}$  up to 450  $\mu\text{m}$ . Most preferred is a moving substrate having been treated mechanically or electromechanically as e.g. an aluminum support having been anodized. Such a coating substrate, available as anodized aluminum, has shown particularly favourable adhesion characteristics with respect to physical vapour deposited phosphors or scintillators coated in the process according to the present invention. In practical applications wherein a flexible supporting web is required, according to the method of the present invention anodized aluminum having a thickness of less than 600  $\mu\text{m}$ , and more preferably at most 400  $\mu\text{m}$  is desired, more particularly if the layer should be bent on rollers. Such a flexible anodized aluminum supporting web indeed allows very good adhesion of deposited scintillator layers after vapour deposition coating as applied in the coating method of the present invention: even bending of that flexible support coated with a scintillator layer having a thickness of 500  $\mu\text{m}$  up to 1000  $\mu\text{m}$ , does not cause "cracks" or delamination of scintillator or phosphor "flakes".

Temperature increase of the substrate due to presence of the flexible substrate in the vapour flow during a long time may however be disadvantageous and may require a configuration with a cooling circuit for the substrate, e.g. via a cooled plate or roller.

The coating process within a sealed zone maintained under vacuum conditions thus provides the possibility to deposit a phosphor or scintillator, known as a material emitting photons upon

- 21 -

exposure to electromagnetic radiation, in form of a layer onto a surface of a flexible substrate, serving as a supporting or supported material, while moving said flexible substrate support as claimed. According to the coating process of the present invention  
5 the step of vapour deposition is initiated by a vapour flow of raw materials from one or more container(s), and wherein said vapour flow is generated by adding energy to said raw materials, by thermal, electric, or electromagnetic energy or a combination thereof.

10

Depending on whether a chemical reaction takes place between components of the raw materials in the crucible(s) while those raw materials get liquefied by added energy, in the vapour stream or in the deposition step, the vapour deposition process is a chemical or  
15 a physical deposition process. In the coating process according to the present invention said step of vapour deposition thus proceeds by physical vapour deposition, by chemical vapour deposition or a by combination of physical and chemical vapour deposition.

20

In a common arrangement within the sealed zone under vacuum pressure (vacuum conditions corresponding with at least  $10^{-1}$  mbar, and even down to  $10^{-4}$  mbar or less if attainable in the preferred configuration of the coating apparatus), the container is one crucible, preferably in form of an elongated "boat". In another  
25 embodiment, it is composed of a plurality of crucibles, arranged in each direction of the two-dimensional, coated surface. It is evident that the composition of the raw material in the containers is chosen in order to provide a composition as desired, wherein said composition is determined by the ratios of raw materials present.  
30 Ratios of raw materials are chosen in order to provide the desired chemical phosphor or scintillator composition after deposition of the vaporized raw materials. It is desirable to mix the raw materials in order to get a homogeneous raw mix in the crucible(s) in form of solid powders, grains or granules, or as pastilles having  
35 a composition corresponding with the desired ratios of raw materials

- 22 -

in order to provide the desired phosphor coated onto the moving substrate material. A milling procedure may be favourable in order to provide a high degree of homogeneity before vaporization and is therefore recommended. Differing components may also be vaporized  
5 from different crucibles, arranged in series or in parallel or in a combined arrangement as already suggested before, provided that a homogeneous vapour cloud is presented to the flexible substrate via the vapour stream or flow, deposited by condensation onto said substrate. Two elongated one-part boats having same or different  
10 raw material content or raw material mixtures may e.g. be present in series in the moving direction of the web. In another embodiment, if providing a more homogeneous coating profile, boats may be arranged in parallel on one axis or more axes, perpendicular to the moving direction of the support, provided that overlapping  
15 evaporation clouds again are providing a vapour stream that becomes deposited onto the support in a phosphor or scintillator layer having a homogeneous thickness, composition and coated amount of said phosphor or scintillator. Presence of more than one crucible may be in favour of ability to supply greater amounts of phosphor or  
20 scintillator material to be deposited per time unit, the more when ~~the flexible substrate should pass the vapour flow at a rate, high~~ enough in order to avoid too high temperature increase of the substrate. The velocity or rate at which the substrate passes the container(s) should indeed not be too slow in view of undesired  
25 local heating of the substrate support, making deposition impossible, unless sufficient cooling means are present in favour of condensation. The supporting or supported substrate should therefore preferably have a temperature between 50°C and 300°C in order to obtain deposited phosphor or scintillator layers having the  
30 desired optimized properties.

As already mentioned hereinbefore energy should be supplied to one or more container(s), also known as crucible(s), tray(s) or boat(s), in order to provoke a vapour flow (or stream) of the raw  
35 materials present therein, which become vaporized in the sealed vacuum zone: energy is submitted thereto by thermal, electric, or

- 23 -

electromagnetic energy sources. As an example of an electromagnetic energy source a diode, a cathodic arc, a laser beam, an electron beam, an ion beam, magnetron radiation or radio frequencies may be used, whether or not pulsed, without however being limited thereto.

5 Electric energy is commonly provided by resistive heating, making use of resistance coils wound around the container(s) or crucible(s) in a configuration in order to get conversion into thermal energy, thereby providing heat transfer to the containers or crucibles filled with the raw materials that should be evaporated. Energy  
10 supply to an extent in order to heat the container(s) or crucible(s) up to a temperature in the range from 550-900°C is highly desired. At those temperatures, it is clear that containers should resist corrosion, so that refractory containers are preferred. Preferred container or crucible materials therefor are tungsten, tantalum,  
15 molybdenum and other suitable refractory metals. Energy supply as set forth heats the mixture of raw materials in the crucible to a temperature above 450°C, preferably above 550 °C, and even more preferably in the range of 550°C up to 900°C.

20 A cloud of vaporized material, originating from the target raw materials thus escapes as a cloud in form of a flow or stream from the container(s) or crucible(s) in the direction of the moving substrate, where a coated layer is formed by condensation. From the description above it is clear that, in order to obtain a homogeneous  
25 coating profile as envisaged, a homogeneous cloud can only be realized when homogeneity is provided in the bulk of the liquefied raw material. As a consequence, a homogeneous distribution of energy supplied over the container is a stringent demand. In a preferred embodiment, in favour of homogeneity, the crucible is in form of a  
30 single elongated "boat" with a largest dimension corresponding with the width of the flexible support moving over the said crucible so that at each point of its surface area the momentarily velocity magnitude is constant.

In any configuration providing the possibility for the  
35 substrate support to pass the raw material container(s) more than once, more than one phosphor or scintillator layer is optionally

- 24 -

deposited, if desired. Addition to the crucible(s) of raw materials determining, and, optionally, changing the chemical composition of the scintillator to be deposited in the vapour deposition process, provides the possibility to gradually change the scintillator composition in thickness direction of the deposited scintillator layer.

Even when no change in composition in the thickness direction is desired, it is clear that the raw material containing crucible(s) become exhausted during the physical vapour deposition process, set forth hereinbefore. Therefore "replenishment" of the crucible(s) should be provided, e.g. by addition of raw material components in powdery form, in form of grains or crystals or in form of pastilles containing caked powder or grain mixtures, in favour of maintaining homogeneity during the further evaporation process as otherwise, differences in dopant (Europium) concentrations may appear while the coating process is running further on. Methods in order to "replenish" the crucible(s) have e.g. been described in US-A 4,430,366, in DE-A 1 98 52362 and in US-A 2003/0024479 A1. An example of an available replenishing unit has been illustrated in the Figures 8 and 9, wherein, as a non-limitative example, also applicable in the other Figures, a source of material supply (26) and a guiding mechanism for raw material supply (27) have been mounted in the vacuum deposition chamber. If required during the deposition process oxygen can be introduced into the vacuum deposition chamber in form of oxygen gas or in form of oxides, to be added to the crucibles. Such a chemical vapour deposition step may be favourable with respect to e.g. the preparation of silicate phosphors. Also an annealing step in between two deposition steps or at the end of the phosphor deposition may be beneficial.

Another factor with respect to coating amount and thickness is the distance between container(s) and moving substrate. The distance determines the profile of the vapour cloud at the position of the flexible substrate. Average values of shortest distances between crucible(s) and substrate are preferably in the range of

- 25 -

from 5 to 10 cm. Too large distances would lead to loss of material and decreased yield of the process, whereas too small distances would lead to too high a temperature of the substrate.

5 Care should further be taken with respect to avoiding "spot errors" or "pits", resulting in uneven deposit of phosphors or scintillators, due to spitting of the liquefied raw materials present in the heated container(s). One way to avoid spots to reach  
10 the moving web or support is to provide the container(s) with a metallic raster, supported by the surrounding edges of said container(s) and covering, at least in part, the container(s). Different configurations are available in order to get the most advantageous solution in order to avoid those spot defects.

15 In a preferred embodiment a guiding plate, guiding the vapour stream towards the substrate may be present in order to better or more sharply define the region wherein phosphor or scintillator material should become deposited. So a baffle as in Fig. 8 (but  
20 also advantageously mounted in the configurations represented in the other Figures) restricts the vapour deposition region on the moving substrate to a small segment or sector, in order to prevent  
undesired deposition of scintillator material as e.g. on the wall of the vacuum chamber.

25 The more space is left free in the vacuum chamber, the more controll sites are available. Free space can be provided e.g. with heat controlling means and sensors for temperature controll at different sites, with regard to optimize homogeneous vapour  
30 deposition onto the moving flexible support. Otherwise, means in order to locally enhance the temperature, as e.g. by infrared radiation, can be provided in the vacuum chamber, where free space allows such installation (e.g. in the neighbourhood of the cooling roll, or whatever a critical site within the vacuum chamber). Means  
35 in order to controll layer thickness of deposited material can also be installed in order to stop the deposition process when the desired thickness is attained.

- 26 -

According to the coating process of the present invention, at the moment of deposition, said phosphor or scintillator layer is a binderless layer. This can be well understood, as at those high temperatures, presence of additional binders besides phosphors or scintillators raw materials in the container(s) would not be practical. It is however not excluded to make use of polymers, showing ability to become vaporized, in order to serve as binder material e.g. between substrate and phosphor or scintillator layer or even between the preferred phosphor or scintillator needles in the coated layer. Moreover when laminating a polymer layer onto the deposited layer, it is not excluded that polymer material is filling, at least in part, the voids between those needles. With respect to the specific application, related with CR and DR, it is clear that in view of image quality, and more particularly in view of sharpness, binderless phosphor or scintillator layers are preferred. With respect thereto it is clear that vaporization of raw materials in order to build the desired scintillators phosphors is a preferred technique, provided that, according to the present invention the layers have been deposited on a flexible substrate, deformed at least before, during or after said step of vapour deposition, by being mounted onto a roller or by being guided over one or more roller(s), as claimed, and wherein it is envisaged to deform the flexible support in order to get a flat sheet or panel, ready-for-use, suited for specific CR and DR applications as set forth.

In one embodiment according to the coating process of the present invention said phosphor is a prompt emitting luminescent phosphor. Said luminescent phosphor is suitable for use e.g. in intensifying screens as used in screen/film radiography.

According to the coating process of the present invention, in another embodiment said phosphor is a photostimulable phosphor and, even more preferred according to the coating process of the present invention, said photostimulatable (storage) phosphor is a CsBr:Eu phosphor. Related therewith and particularly preferred in the

- 27 -

coating process according to the present invention, although not limited thereto at all, said raw materials are CsBr and between  $10^{-3}$  and 5 mol % of a Europium compound selected from the group consisting of  $\text{EuX}'_2$ ,  $\text{EuX}'_3$  and  $\text{EuOX}'$ ,  $\text{X}'$  being a halide selected from the group consisting of F, Cl, Br and I as has been used in the preparation method disclosed in PCT-filing WO 01/03156. Even more preferred is the binderless coating process according to the present invention of the selected CsBr:Eu phosphor from CsBr and EuOBr raw materials, wherein the said phosphor is characterized by its particular needle-shaped form. The high degree of crystallinity is easily analysed by X-ray diffraction techniques, providing a particular XRD-spectrum as has been illustrated in EP-A 1 113 458. Therefore a mixture of CsBr and EuOBr is provided as a raw material mixture in the crucibles, wherein a ratio between both raw materials normally is about 90 % by weight of the cheap CsBr and 10 % of the expensive EuOBr, both expressed as weight %. It has however been shown that as a function of coating (evaporating) temperature ratios can be adapted in favour of lower material and production cost, without resulting in changes in composition: so higher vaporization temperatures for the raw material mixture in ratio amounts of 99.5 wt% CsBr and 0.5 wt% EuOBr provide the same result as before.

The preferred CsBr:Eu<sup>2+</sup> phosphor, obtained after vapour deposition as a needle-shaped phosphor, is characterized by voids between the needles. In order to fill those voids, measures can be taken as described in EP-Application No. 02 100 235, filed March 8, 2002, wherein voids are partially filled with a polymeric compound; as in EP-Application No. 02 100 296, filed March 26, 2002, wherein vapour deposited pigments like the preferred  $\beta$ -Cu-phthalocyanine nanocrystalline dye compound are filling said voids or as in EP-Application No. 03 100 471, filed February 26, 2003, wherein the voids are at least partially filled with polymeric compounds selected from the group consisting of silazane and siloxazane type polymeric compounds, mixtures thereof and mixtures of said silazane or siloxazane type polymeric compounds with compatible polymeric

- 28 -

compounds. More particularly with respect to the said dyes or pigments, vapour deposition thereof can be performed in the vacuum deposition chamber used in the configuration of the production method according to the present invention.

5

In a further embodiment according to the coating method or process of the present invention, said process is characterized by the step of applying a protective coating onto said phosphor or scintillator layer. Preferably, said protective coating is coated  
10 or laminated onto said phosphor or scintillator layer inside said sealed zone, maintained under vacuum conditions. Most preferably said protective coating is organic resin layer. More in particular, said protective layer is provided in order to protect the coated scintillator or phosphor against moisture. Such a protective  
15 coating composition is not restricted to one layer, but may comprise more than one layer as has e.g. been described in EP-A 1 286 363, wherein said protective layer is divided in at least two layers, being a layer A, closest to said phosphor layer and a layer B, farther away from said phosphor layer; characterized in that said  
20 layer A has a lower water vapour permeability coefficient than said layer B. Just as in EP-A 1 286 364, said layer A preferably is a layer of parylene, and more preferably said parylene is selected from the group consisting of parylene C, parylene D and parylene HT. It is not excluded to have such a parylene layer coated onto said  
25 flexible substrate as in EP-Application No. 02 100 763, filed June 28, 2002, wherein a moisture repellent layer is present inbetween the substrate and the phosphor layer. It is moreover not excluded to have a film-forming silazane or siloxazane type polymeric compound, covering the outermost surface of the poly-paraxylylene  
30 film on the phosphor side as has been disclosed in EP-Application No. 03 100 472, filed February 26, 2003.

In a particular embodiment said vapour deposited protective composition is thus applied in the same sealed zone in the same  
35 coating apparatus. Such a protective composition and/or laminate is advantageously applied to the preferred CsBr:Eu<sup>2+</sup> storage phosphor,

- 29 -

which is known to be moisture sensitive. Other hygroscopic phosphors that are advantageously prepared according to the method of the present invention are e.g. BaFCl:Eu, BaFBr:Eu and GdOBr:Tm, used in intensifying screens; CsI:Na applied in scintillator panels and storage phosphors suitable for use in computed radiography (CR) as e.g. BaFBr:Eu, BaFI:Eu, (Ba,Sr)F(Br,I):Eu, RbBr:Tl, CsBr:Eu, CsCl:Eu and RbBr:Eu; or CsI:Tl, which is particularly suitable for use in DR-cassettes.

In the coating process according to the present invention the step of applying a protective coating or laminate onto said phosphor or scintillator layer is advantageously performed, wherein said protective coating is an organic resin layer.

In another embodiment in the coating process according to the present invention the step of applying a protective coating or laminate onto said phosphor or scintillator layer is advantageously performed, wherein said protective coating is an inorganic layer.

Protection by an overcoat layer of "parylene" is particularly recommended. Details about the composition of this layer can be found in EP-A's 1 286 362, 1 286 363, 1 286 364 and 1 286 365: in the method of applying a protecting parylene layer to the phosphor coatings therein as a "parylene layer" a halogen-containing layer was preferred. More preferably said "parylene layer" was selected from the group consisting of a parylene D, a parylene C and a parylene HT layer. In the particular case as in the method of the present invention a cross-linked polymeric layer is thus formed on a phosphor screen material, wherein the said polymeric material layer has been formed by reaction of at least one component, thereby forming self-condensing polymers. Reactive monomers are provided in form of heated vapour in order to form the desired condensation polymer on the substrate, wherein said condensation polymer is in form of a p-xylylene or "parylene" layer on the phosphor screen substrate. Examples of these "parylene" layers are poly-p-xylylene (Parylene-N), poly-monochloro-p-xylylene (Parylene-C) and

- 30 -

polydichloro-p-xylylene (Parylene-D). If desired a pigment can be integrated into a thin film of a poly-p-xylylene as has been described in JP-A 62-135520.

5           Within the scope of the present invention a choice may be made, whether to deposit the parylene layer "in situ" or to laminate it as a foil onto the vaporized phosphor layer as illustrated before. It is recognized that besides "parylene", other useful polymers may also be used, either as a separate layer besides the said parylene  
10 layer, or as a second protecting layer as has e.g. been described in EP-A 1 286 363. Both layers may have a different water vapour permeability coefficient. In a preferred embodiment thereof the phosphor layer closest to the phosphor layer has a lower water permeability coefficient. It is not excluded to cover the aluminum  
15 layer before coating a layer of phosphor or scintillator material with a protective layer being a "parylene" layer as a polymeric compound layer, on a side of said aluminum layer whereupon vapour deposition of phosphor or scintillator material is applied afterwards. Moreover it is perfectly possible to apply the  
20 "parylene" layer in the same coating apparatus as mentioned before.

With respect to all configurations illustrated and explained hereinbefore, additional rollers may be provided in order to laminate the phosphor or scintillator layer with a protective layer  
25 as set forth hereinbefore, optionally in the same vacuum environment as wherein the phosphor deposition takes place. The coated scintillator or phosphor substrate and a laminating sheet or web, may be brought together, thereby laminating the phosphor or scintillator layer. In this process e.g. a transparent pressure  
30 sensitive adhesive layer, optionally released instantaneously from a temporary support layer, may be applied.

After having coated such a protective layer (or even in the absence thereof) a laminating (polymer) layer is advantageously  
35 applied, more particular with respect to protection of the phosphor

- 31 -

or scintillator layer against abrasion in working conditions as e.g. in a scanner apparatus.

5 So in addition to a "parylene film" as a protective layer, a laminating polymer layer (e.g. PET - polyethylene therephthalate - or PEN - polyethylene naphthalate) is advantageously provided thereupon as an additional protective organic resin, whether used as a temporarily or permanent rigid (laminate) layer.

10 In order to end up with a rigid screen, plate or panel ready-for-use in scanners, the flexible plates are advantageously laminated against a rigid carrier. The rigid carrier can be either flat or non flat, e.g. concave or convex at the side to which the flexible plate is laminated onto.

15 Accordingly the coating process of the present invention is further characterized by the step of laminating said substrate carrying the phosphor or scintillator layer onto a carrier layer.

20 More in particular according to the present invention said carrier layer is a flexible or rigid polymer layer.

In another embodiment according to the present invention, said carrier layer is a metal sheet, and even more preferably said  
25 carrier layer is a rigid metal sheet.

According to the coating process of the present invention, said step of laminating said substrate carrying the phosphor or scintillator layer is performed inside said sealed zone, maintained  
30 under vacuum conditions.

It is more suitable that cutting of the coated substrate into tailor made screen sheets, plates or panels in desired formats takes place out of the vacuum chamber. In a particular embodiment cutting  
35 may proceed on-line, e.g. when a sheet or web is leaving the sealed zone as the coated, and, optionally, laminate coated phosphor or

- 32 -

scintillator, it can immediately be cut into screens, plates or panels having the desired format.

According to the coating process of the present invention the process further comprises the step of cutting after deposition of said phosphor or scintillator layer, or after applying said protective organic resin layer or layers onto said phosphor or scintillator layer.

The object to coat a surface as large as possible in a way to get a homogeneous deposit of phosphor or scintillator material over quite a large screen, sheet, plate or panel surface area becomes available by application of the method of the present invention. Said method moreover allows quite a lot of configurations in the vapour deposition coating apparatus as set forth.

In a practical application phosphor or scintillator screens or panels having a coated length in the range from e.g. 1.00 m up to at least 500 m and a coated width in the range from 0.50 m up to 3 m become available, depending on the dimensions of the sealed zone in the coating apparatus. So if mounted onto the cylindrical roller (as in Fig. 1) the substrate e.g. provides the possibility to perform the vapour deposition coating process over a width of about at least 90 cm and a length of at least 120 cm, depending on the corresponding circumference of the cylinder. In that case multiple rotations of the cylinder in order to get vapour deposition of a sufficiently thick layer may be required. A very important advantage of the present invention is thus attained by the availability of large, homogeneously coated layers onto the flexible substrates as set forth by the coating method of the present invention.

In order to summarize the advantageous effects of the present invention, it becomes clear from the description above that the problem of homogeneity, related with coating profiles of coatings in two dimensions as normally applied, is overcome by the method of the

- 33 -

present invention: coatings in one preferred dimension, more particularly over the whole width of the supporting web, by application of the "on-line vapour deposition" method as set forth have been shown to be advantageously applicable in practice.

5 Opposite thereto a support having limited bending capacity as e.g. a glass support having a thickness of some millimeters, can only be coated up to formats not exceeding the dimensions of the vacuum chamber, unless the glass support would leave the sealed zone of the coating apparatus. Although providing the possibility to get more  
10 than one layer deposited, e.g. when such a deposition proceeds in a "swinging" way, lack of deformability limits the format of the coating of a phosphor or scintillator layer on a substrate to the largest cross section of the vacuum deposition chamber.

15 The said vapour deposition process according to the present invention thus proceeds in a sealed zone under vacuum conditions and as it is directed in a more dedicated way, i.e. in an "on-line linear deposition process", instead of onto a two-dimensional circular or rectangular support. As a result, practically the whole  
20 coated supporting web can effectively be made available in flat panel detectors for CR and DR applications without expensive lost residue or residue that has to be recycled and the yield or efficiency of the deposition process is thus remarkably enhanced. First experiments unambiguously indicated that a yield increase was  
25 attained with a factor of about 5, as in the comparative batch depositing process in a rotational deposition configuration on rectangular substrates the yield was limited to about 15 %, whereas the present invention provided yields up to 75%! Besides saving expensive raw materials in view of cost price of those raw materials  
30 and of recycling costs thereof, the "time saving" factor offered by the continuous manufacturing method of the present invention is significant.

Due to the particular configuration of the sealed zone,  
35 maintained under vacuum conditions, quite a lot of space is free therein so that any measuring apparatus (as e.g. one or more thermal

- 34 -

sensors) at different (critical) sites may provide increased control and direct adjustment of coating conditions in the vapour deposition stream for the method as applied according to the present invention. Enhanced measurement control and adjustment of critical process  
5 parameters directly contributes to an improved process control, an enhanced reproducibility and an optimized homogeneity, in favour of constant speed and image definition over the whole plate surface, even when large plates are envisaged.

10 Coatings of larger surfaces, as provided by the method of the present invention are further enabling the manufacturer to make a choice with respect to the dimensions of the plates: any size can be cut and delivered as "tailor made" ordered by the customer in order to be perfectly adapted to scanners used in image formation  
15 applications.

Coating on a large substrate, optionally cutted, and subsequent lamination onto a rigid plate of the flexible substrate on which the phosphor or scintillator layer has been deposited, is made possible  
20 by the unexpected flexibility of the phosphor layer and the perfect adhesion of the phosphor layer to the substrate.... High flexibility and perfect adhesion is observed, even for phosphor layers having thicknesses up to at least 1 mm.

25 It is understood that the screens, panels, plates or sheets prepared by the method as set forth hereinbefore, are particularly suitable for use as phosphor or scintillator plates, in intensifying screens, in stimuable or storage phosphor screens, suitable for use in high energy radiation detection and image formation and, more  
30 particularly, in screen/film radiography, in computed radiography and in direct radiography. In those applications it is clear that the screens, plates or panels are mounted in a cassette, where appropriate.

35 As a result coated phosphor or scintillator layers for use in screens, plates or panels become available in unexpectedly large

- 35 -

surface area formats. Moreover the said layers prepared according to the process or method of the present invention have an almost constant coating profile after having been prepared with an unexpected high yield and remarkably reduced loss of expensive raw materials.

While the present invention will hereinafter be described in connection with preferred embodiments thereof, it will be understood that it is not intended to limit the invention to those embodiments.

## Examples

### Comparative Example 1

This example describes the state-of-the art method performed in order to obtain a photostimulable CsBr:Eu imaging plate.

A CsBr:Eu photostimulable phosphor layer was deposited in a vacuum chamber via thermal vapour deposition on a flat rigid aluminum support that rotates around an axis perpendicular to and going through the centre of the support starting from a mixture of CsBr and EuOBr as raw materials. While rotating said support its momentary velocity magnitude is highest at the outside (at the boundary) of the support and zero in the centre of the support.

The support was heated with the aid of a resistively heated heating plate having a temperature of 240°C.

The support was aluminum having a thickness of 800 µm, a width of 18 cm and a length of 24 cm. The aluminum support was mounted, against a substrate holder, rotating in a controlled way by means of a motor, around its axis. The aluminum was rotating with an angular speed of 12 rotations per minute. The support was heated by means of a resistively heated heating plate at 240°C.

- 36 -

A mixture of CsBr and EuOBr, in a CsBr/EuOBr 99,5%/0,5% ratio by weight percentage was used as a raw material mixture to become vaporized and was placed in two containers. The distance between the containers and the substrate was about 15 cm. The containers  
5 were placed at the circumference of a circle described by an edge of the rotating substrate. The containers were covered with a cover plate having one slit therein and a guiding plate, guiding the vapour stream towards the substrate.

10 Under vacuum pressure (a pressure of  $2 \times 10^{-1}$  Pa was maintained as an equilibrium between a continuous inlet of argon gas into the vacuum chamber and continuous pumping) and at a sufficiently high temperature of the vapour source (750°C) the obtained vapour was directed towards the rotating substrate and was deposited thereon.

15 A CsBr:Eu stimuable phosphor layer having an average thickness of 500  $\mu\text{m}$  was deposited over the entire area of the support.

Only 13 % by weight of the evaporated material was deposited onto the support.

20 An area of  $0,043 \text{ m}^2$ , suitable for practical use, was obtained.

The stimuable phosphor layer shows a blue luminescence under UV radiation.

## 25 Inventive Example 2

A CsBr:Eu photostimulable phosphor screen on flexible anodized aluminum was prepared in a vacuum chamber via thermal vapour deposition on a flexible anodized aluminum support, moving in such a  
30 way that the momentary magnitude of the velocity was constant over its whole area, starting from a mixture of CsBr and EuOBr as raw materials.

Referring to Fig. 1 the cylindrical vacuum chamber (1) with a  
35 diameter of 1.4 m and a length of 1.75 m was containing an

- 37 -

electrically heated oven (2) and a refractory tray or boat (3) (dimensions of the elongated boat composed of "stainless steel 1.4828": 0.97 m (length) x 4.5 cm (width) x 6.8 cm (depth), having a wall thickness of 3 mm), in which 4 kg of a mixture (4) of CsBr and  
5 EuOBr in a 99,5%/0,5% CsBr/EuOBr percentage ratio by weight were present as raw materials to become vaporized. The boat was covered with a metallic raster (14) having a mesh of 300  $\mu\text{m}$  in order to reduce the formation of pits during evaporation.

10 Under vacuum pressure (a pressure of  $2 \times 10^{-1}$  Pa) maintained by a continuous inlet of argon gas into the vacuum chamber, and at a sufficiently high temperature of the vapour source (760°C) the obtained vapour was directed towards a moving sheet support (5) and was deposited thereon successively while said support was moving  
15 along the vapour stream (16).

The anodized aluminum support (5) having a thickness of 380  $\mu\text{m}$ , a width of 1.18 m and a length of 1.26 m, was mounted, with the anodized side at the side whereupon the phosphor should be  
20 deposited, around a cooled cylindrical support roller (6) having a diameter of 40 cm and a length of 1.18 m rotating in a controlled way by means of a motor around its axis. The anodized aluminum was moving with a constant linear velocity of 2 m per minute.

25 The cooled cylindrical support roller (6) was thermally isolated from the support sheet (5) by means of a thermal isolation layer (7) and by means of a heat-resistant coiled springs (8), mounted circumferentially around the cylinder.

30 The coiled springs (8) also interconnect both ends of the anodized aluminum plate in order to stretch the anodized aluminum around the support roller (6) and in order to overcome a loss of tension during heating up of the anodized aluminum, due to thermal expansion. The support (5) was actually resting on these coiled  
35 springs.

- 38 -

The support (5) was heated up to 150°C by means of an infrared heater (9) and a reflector cage (10). The temperature was measured with a pyrometer (11).

5 A pair of baffles (12) and (13) limits the vapour deposition area on the support (5) to a small region or sector of 28 cm of the support roller. In that way undesired deposition of phosphor (as e.g. on the wall of the chamber) was prevented.

10 Another pair of separation plates (15) was dividing the vacuum chamber (1) in an evaporation chamber part (18) and a heating chamber part (19).

A CsBr:Eu stimuable phosphor layer having a mean thickness of  
15 725  $\mu\text{m}$  was deposited over the entire length of the support in successive steps, during which the thickness of the deposited layer was increasing, within a time of 79 minutes. The support was successively passing the vapour stream over the refractory boat or tray 125 times. The layer was thereby growing with an increasing  
20 thickness of 5.8  $\mu\text{m}$  per rotation. During each rotation the layer was only growing effectively during a time of 0.14 minutes (= 0.28 m per 2 m per minute). This corresponds with a time of 8.4 seconds while the support was passing the deposition window of 0.28 m. During the condensation process, the effective deposition speed,  
25 expressed as layer thickness per time unit, was 41  $\mu\text{m}$  per minute or 0.7  $\mu\text{m}$  per second.

A thickness homogeneity between 675  $\mu\text{m}$  and 775  $\mu\text{m}$  was obtained over a distance of 73 cm in a direction perpendicular to the moving  
30 direction and over a length of 1.20 m in the moving direction.

75 % by weight of the evaporated material was deposited onto the support.

35 The stimuable phosphor layer was showing a blue luminescence under UV radiation.

- 39 -

The area of the above described imaging plate, effectively suitable for practical use was  $0,87 \text{ m}^2$  (about 20 times the  $0,043 \text{ m}^2$  available from the comparative example hereinbefore).

5        Panels having the desired size, e.g. 35 cm x 45cm, were cut out of the above described plate with a good edge quality. The cutted panels were then laminated against a rigid flat glas plate without damage of the layer, making use therefor of a transferable adhesive.

10

      In the same way as described hereinbefore sizes of the vacuum deposited plates were increased up to an area of more than  $2 \text{ m}^2$  by increasing the length of the anodized aluminum support to more than 2.74 m. This was performed by increasing the diameter of the  
15 support roller (6) from 0.4 m to 0.9 m.

      In another experiment increase of the length of the anodized aluminum web was realized by adding supporting rollers in the evaporating part (18), in the heating part (19) and in both parts of  
20 the vacuum chamber (1). Stretching the anodized aluminum around those different support rollers made available a coating space in the most convenient and space-saving way (see Fig. 2 and Fig. 3).

      If in the above mentioned vacuum chamber (1) a configuration  
25 with a rotating substrate should have been used, typically applied for the preparation of photostimulable imaging plates as described in comparative example 1, it could have been possible to obtain a maximum area, suitable for practical use of  $1.54 \text{ m}^2$  only.

30        Inventive example 2 clearly shows that by use of a moving flexible substrate, moving in such a way that the said flexible substrate is moving at a momentary velocity magnitude remaining constant over the whole available area, wherein said substrate is deformed before, during and after said step of vapour deposition,

- 40 -

photostimulable phosphor plates with a very good thickness homogeneity can be obtained that have an improved area suitable for use and an improved material yield if compared with the use of a substrate, rotating around an axis, perpendicular to and going  
5 through the center of the substrate, as in comparative example 1.

### Inventive Example 3

A CsBr:Eu photostimulable phosphor screen was prepared in a  
10 vacuum chamber by thermal vapour deposition on a flexible anodized aluminum, that was supplied in a continuous fashion.

Referring to Fig. 8 a cylindrical vacuum chamber (1) with a diameter of 1.4 m and a length of 1.75 m was containing an electrically heated oven (2) and a molybdenum tray or boat (3)  
15 (dimensions of the elongated boat: 0.97 m (length) x 1.40 cm (width) x 5.8 cm (depth), having a wall thickness of 3 mm), in which 1,6 kg of a mixture (4) of CsBr and EuOBr in a 99,5%/0,5% CsBr/EuOBr percentage ratio by weight were present as raw materials in order to become vaporized. The vacuum chamber (1) further contained a roller  
20 supply (23) of anodized aluminum that was fed out in continuous sheet form (22), also called "web". The web was conveyed over a cooled guiding roller (6) with a diameter of 40 cm and collected on a winding roll (24), collecting the web after vapour deposition coating.

25 The anodized aluminum support (22) having a thickness of 280  $\mu\text{m}$ , a width of 0.65 m and a length of 10 m, was mounted in such a way that the anodized side was at the side whereupon the phosphor should be deposited. The web of anodized aluminum was moving with a velocity of 20 cm per minute.

30 Under vacuum pressure (a pressure of  $2 \times 10^{-1}$  Pa) maintained by a continuous inlet of argon gas into the vacuum chamber, and at a sufficiently high temperature of the vapour source (760°C) the obtained vapour was directed towards the moving anodized aluminum (21) and was deposited thereon while said anodized aluminum was  
35 moving continuously through the vapour stream.

- 41 -

A pair of baffles (12) and (13) limits the vapour deposition area on the support (22) to a small region or sector of 28 cm of the support roller (6). In that way undesired deposition of phosphor (as e.g. on the wall of the chamber) was prevented.

5 Another pair of separation plates (15) was dividing the vacuum chamber (1) in an evaporation part (18) and a winding part (25).

A cooled baffle (17) was moved in order to shut off the surface to be coated from, or to expose the surface to be coated to the vapour stream.

10 A CsBr:Eu stimuable phosphor layer having a mean or average thickness of 65  $\mu\text{m}$  was deposited in a continuous way over a length of 3 m and a width of 0.65 m. The layer of 65  $\mu\text{m}$  was thereby grown in 1.4 minutes, corresponding with the time that the surface to be coated was exposed to the vapour stream while passing the vapour stream (16). The effective deposition speed, expressed as layer  
15 thickness per time unit, was 46  $\mu\text{m}$  per minute.

The deposited layer was wound up on the wind up roller (24) without the formation of cracks in the deposited phosphor layer.

The stimuable phosphor layer was showing a blue luminescence  
20 under UV radiation.

The area of the above described deposited phosphor layer, effectively suitable for practical use was ca. 2 m<sup>2</sup>.

Panels having the desired size of 35 cm x 43cm were cut out of the above described deposited layer with a good edge cutting  
25 quality. The cutted panels were laminated, making use of a transferable adhesive, against a rigid flat glas plate without damage of the layer.

Inventive example 3 clearly shows that by use of a moving  
30 flexible substrate, supplied in roller form, huge areas deposited with a phosphor layer, are available. Out of these layers the right formats as desired can be cut and laminated against a rigid substrate.

- 42 -

Having described in detail preferred embodiments of the current invention, it will now be apparent to those skilled in the art that numerous modifications can be made therein without departing from the scope of the invention as defined in the appending claims.

## PARTS LIST

- (1) vacuum chamber
- (2) oven
- (3) crucible, tray or boat
- 10 (4) mixture of raw materials
- (5) sheet
- (6) roller
- (7) thermal isolation layer
- (8) cylindrical springs
- 15 (9) infrared heater
- (10) reflector cage
- (11) pyrometer
- (12) baffle
- (13) baffle
- 20 (14) metallic raster
- (15) separation plates
- (16) vapour stream
- (17) baffle
- (18) evaporation part
- 25 (19) heating part
- (20) conveying rollers
- (21) travelling pathway
- (22) web
- (23) unwinding roller (supplying roller)
- 30 (24) (up)winding roller (collecting roller)
- (25) winding part
- (26) source of raw material supply
- (27) guiding mechanism (for raw material supply)
- (28) ambient atmosphere

- 43 -

**[CLAIMS]**

1. A method for coating a phosphor or a scintillator layer onto a flexible substrate, within a sealed zone maintained under vacuum conditions, by the step of vapour deposition, wherein said phosphor or scintillator layer is deposited onto said substrate, characterized in that said substrate is deformed at least before, during or after said step of vapour deposition.
2. Coating process according to claim 1, wherein said phosphor or scintillator layer is deposited onto said flexible substrate, and wherein said substrate is continuously supplied.
3. Coating process according to claim 1 or 2, wherein said phosphor or scintillator layer is deposited onto an area of said flexible substrate, exceeding the area of a phosphor or scintillator screen, panel or plate ready-for-use by at least 50%.
4. Coating process according to claim 1 or 2, wherein said phosphor or scintillator layer is deposited onto an area of said flexible substrate, exceeding the area of a phosphor or scintillator screen, panel or plate ready-for-use by at least a factor of 5.
5. Coating process according to claim 1 or 2, wherein said phosphor or scintillator layer is deposited onto an area of said flexible substrate, exceeding the area of a phosphor or scintillator screen, panel or plate ready-for-use by at least a factor of 10.
6. Coating process according to any one of the claims 1 to 5, wherein said substrate is, at least partially, moving over one or more roller(s) and/or guiding frame(s).
7. Coating process according to any one of the claims 1 to 6, further comprising the step of cutting said substrate, carrying said deposited phosphor or scintillator layer.

- 44 -

8. Coating process according to any one of the claims 1 to 7,  
wherein said substrate is moving over at least one unwinding or  
supplying roller and/or one roll up or winding roller, wherein  
none, one or both of said roller(s) is(are) present outside said  
sealed zone.
9. Coating process according to any one of the claims 1 to 8,  
wherein said flexible substrate is passing, at least once,  
through said coating zone by a continuous or discontinuous motion  
in a forward sense...
10. Coating process according to any one of the claims 1 to 8,  
wherein said flexible substrate is moving in successive steps of  
forward and backward motion, whether or not interrupted inbetween  
said successive steps.
11. Coating process according to any one of the claims 1 to 10,  
wherein said substrate is a self-supporting sheet, plate, web or  
panel.
12. Coating process according to any one of the claims 1 to 10,  
wherein said substrate is a roller web.
13. Coating process according to any one of the claims 1 to 10,  
wherein said substrate is supported by a substrate holder.
14. Coating process according to any one of the claims 1 to 13,  
wherein said substrate is selected from the group consisting of  
glass, a polymeric material or a metal.
15. Coating process according to claim 14, wherein said metal  
substrate is an aluminum layer, previously coated with a  
protective layer being an oxide or a polymeric compound layer,  
present on at least a side of said substrate moving through said  
vapour stream.

- 45 -

16. Coating process according to claim 14 or 15, wherein said metal substrate is an anodized aluminum layer having a thickness of less than 600  $\mu\text{m}$ .
- 5 17. Coating process according to any one of the claims 1 to 16, wherein said step of vapour deposition is initiated by a vapour flow of raw materials from one or more container(s), and wherein said vapour flow is generated by adding energy to said raw materials and said container(s), by thermal, electric, or electromagnetic energy or a combination thereof.
- 10 18. Coating process according to any one of the claims 1 to 16, wherein said step of vapour deposition proceeds by physical vapour deposition, by chemical vapour deposition or a by combination of physical and chemical vapour deposition.
- 15 19. Coating process according to any one of the claims 1 to 18, wherein said phosphor or scintillator layer is a binderless layer.
20. Coating process according to any one of the claims 1 to 19, wherein said phosphor is a photostimulable phosphor.
- 20 21. Coating process according to claim 20, wherein said photostimulable phosphor is a CsBr:Eu phosphor.
22. Coating process according to any one of the claims 1 to 19, wherein said phosphor is a prompt emitting luminescent phosphor.
- 25 23. Coating process according to any one of the claims 1 to 22, further characterized by the step of applying a protective coating onto said phosphor or scintillator layer.
24. Coating process according to claim 23, wherein said protective layer is coated or laminated onto said phosphor or scintillator layer inside said sealed zone, maintained under vacuum conditions.

- 46 -

25. Coating process according to claim 23 or 24, wherein said protective coating or laminate is an organic resin layer.

26. Coating process according to claim 22 or 23, wherein said protective coating or laminate is an inorganic layer.

5 27. Coating process according to any one of the claims 1 to 26, further characterized by the step of laminating said substrate carrying the phosphor or scintillator layer onto a carrier layer.

10 28. Coating process according to claim 27, wherein said step of laminating said substrate carrying the phosphor or scintillator layer is performed inside said sealed zone, maintained under vacuum conditions.

29. Coating process according to claim 27 or 28, wherein said carrier layer is a flexible or rigid polymer layer.

15 30. Coating process according to claim 27 or 28, wherein said carrier layer is a metal sheet.

31. Coating process according to claim 27 or 28, wherein said carrier layer is a rigid metal sheet.
